Problem 1: (20 points) Number Representation

(5 points) How many yes/no options (e.g., mustard/no mustard, lettuce/no lettuce, etc.) do you have to “personalize” your Wendy’s hamburger?

(5 points) If Wendy’s added two additional yes/no options, how many total ways would one now have to “personalize” your Wendy’s burger? Assume that these two options are totally independent of the 256 current ways of personalization.

(5 points) Assume that In-N-Out has N ways to personalize their burger. How many bits do they require to represent all of these personalization options?

(5 points) Knowing the secret In-N-Out menu expands the number of options by 17 times, i.e., there are 17N ways to personalize your burger if you know the secret menu options. How many bits does this require?
Problem 2: (20 points) Arithmetic

Translate the following code into MIPS assembly:

\[ Z = ((A+B) \times (C+D)) + ((E+F) \times (G \times H)) \]

Assume that variables A–H, Z are in registers $s0$–$s8$, respectively (e.g., C = $s2$). Also, assume that you cannot overwrite variables A–H since they will all be used later in the program. You must write the MIPS code exactly as it appears above, i.e., you can not perform any optimizations (e.g., using transitive, commutative, distributive properties).

For this question, you can use the `mul` pseudo-instruction. It has this form:

```
mul $1, $2, $3, where $1 = $2 \times $3.
```

It does the same thing as:
```
mult $2, $3
mflo $1
```

Do not use `mult` and `mflo`.

a) **(10 points)** Assume that you have sequential processor where `add` and `mul` take 1 and 3 cycles, respectively. Write the code such that it uses the minimum number of registers and cycles. How many additional registers (other than $s0$–$s8$) does your code require? How many cycles does your code need?
b) **(10 points)** Assume that you have a different type of processor architecture (call it VLIW) that can perform one `add` operation and one `mul` operation during every cycle. Rewrite the code to take advantage of this and use the minimum number of cycles. The VLIW processor uses a faster implementation of `mul`, which only takes 1 cycle, the same as the cycle time of `add`. To make it easier to grade, please write `mul` and `add` that are executed in the same cycle on one line, for example:

```
mul $1, $2, $3, add $4, $2, $8
```

How many cycles does your code need?
Problem 3: (20 points) String Manipulation

(5 points) Describe succinctly, in English, what the following function does:

```c
char * someFunction(char *src, char uc, int n)
{
    while (n-- != 0) {
        if (*src == uc)
            return src;
        src++;
    }
    return NULL;
}
```

(15 points) Write the C code for the function
```
char * insert (int pos, char * base, char * insert)
```
that inserts a copy of the entire contents of `insert` into `base` at character position `pos`.

```c
main()
{
    char * base = "CSE Computer Organization";
    char * insert = "30";
    char * result = insert(3, base, insert);
}
```

The result string is “CSE30 Computer Organization”.

This page was intentional left blank.
Problem 4: (40 points) MIPS Reverse Compilation

Consider the following MIPS assembly code:

```
creeper:      add $t0, $0, $0
            addi $t1, $a1, -1
specter:     slt $t2, $t0, $t1
            beq $t2, $0, disc_demon
            add $t3, $a0, $t0
            lb $t4, 0($t3)
            add $t5, $a0, $t1
            lb $t6, 0($t5)
            sb $t6, 0($t3)
            sb $t4, 0($t5)
            addi $t0, $t0, 1
            addi $t1, $t1, -1
            j specter
disc_demon:  add $v0, $a0, 0
            jr $ra
```

a) (15 points) Translate the above creeper function into C. Your function header should list the types of any arguments and return values. Also, your code should be as concise as possible, without any gotos. We will not deduct points for syntax errors unless they are significant enough to alter the meaning of your code.

b) (5 points) Describe briefly, in English, what this function does.
c) **(20 points)** Convert the following instructions from the code above into 32 bit hexadecimal number. Assume that the address of the first instruction (add $t0, $0, $0) or equivalently the label **creeper** is located at address 0x00400018.

**5 points**  
\[ \text{lb } t6, 0(t5) \]

**5 points**  
\[ \text{beq } t2, 0, \text{ disc_demon} \]

**5 points**  
\[ \text{j specter} \]

**5 points**  
\[ \text{addi } t1, a1, -1 \]
Problem 5: (35 points) Data Structures

A list is a series of elements that are sequentially connected to each other. A list node is a structure that represents a single element of a list. A list node is formally defined as follows:

```c
struct ListNode {
    int data;     // this is the data contained in this element
    ListNode* next;   // this is a pointer to the next element in the list
    ListNode* prev;   // this is a pointer to the previous element in the list
};
```

A list is simply a series of these nodes connected using pointers.

The C function `reverse` that completely reverses the ordering of the elements in the list is shown below. The function takes one argument: a pointer to the first `ListNode` object of the list. It returns a pointer to the new first element of the list (which was previously the last element)

```c
ListNode * reverse(ListNode *aNode) {
    ListNode * tempNode;
    
    tempNode = aNode->next;     //save the next pointer
    aNode->next = aNode->prev;   //switch the prev and next ptrs
    aNode->prev = tempNode;

    if(aNode->prev == NULL)       //stop if end of list
        return aNode;            // has been reached
    else
        return reverse(aNode->prev);   //otherwise continue
                                            // recursively
}
```

a) **(5 points)** How many bytes is one instance of a ListNode struct?
b) **(20 points)** Write a recursive MIPS assembly code for this C function. You must follow register conventions as well as standard procedure calling conventions for full credit on this question. In other words, make no assumptions about the calling procedure.

- Solutions that are not recursive will not get any credit
- You must follow all register conventions and procedure calling conventions
- You must only use real MIPS instructions (no pseudoinstructions)
- You must write comments. Code that is not adequately commented will be penalized.
c) **(10 points)** Translate the following memory layout to the pictorial description of a list. The head of the list is \(0x472AF014\).

<table>
<thead>
<tr>
<th>Address</th>
<th>Value</th>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>

<td>0xE123014C</td>
<td>0x00123AF0</td>
<td>0x00123AF0</td>
<td></td>
</tr>
<tr>
<td>0xE123014C</td>
<td>0x00123AF0</td>
<td>0x00123AF0</td>
<td></td>
</tr>
<tr>
<td>0xE123014C</td>
<td>0x00123AF0</td>
<td>0x00123AF0</td>
<td></td>
</tr>
</tbody>
</table>
Problem 6: (15 points) Handle Swap

void swap(char **one, char **two) {
    char temp = **one;
    **one = **two;
    **two = temp;
}

Write MIPS assembly code for the swap C function.
- You must follow all register conventions and procedure calling conventions
- You must only use real MIPS instructions (no pseudoinstructions)
- You must write comments. Code that is not adequately commented will be penalized.
